The evaluation and management of female sexual dysfunction

Patients often fail to bring it up, and physicians may be reluctant to discuss it, but ignoring sexual dysfunction can disrupt a woman’s most intimate relationships.

**The care of women with female sexual disorders has made great strides since Masters and Johnson first began their study in 1957. In 2000, the Sexual Function Health Council of the American Foundation for Urologic Disease defined the classification system for female sexual dysfunction, which was eventually published and officially defined in the *Diagnostic and Statistical Manual of Mental Disorders-IV-TR*.\(^1\) There are now definitions for sexual desire disorders, sexual arousal disorders, orgasmic disorder, and sexual pain disorders.

Female sexual dysfunction (FSD) has complex physiologic and psychological components that require a detailed screening, history, and physical examination. Our goal in this review is to provide family physicians with insights and practical advice to help screen, diagnose, and treat female sexual dysfunction, which can have a profound impact on patients’ most intimate relationships.

**Understanding the types of female sexual dysfunction**

Most women consider sexual health an important part of their overall health.\(^2\) Factors that can disrupt normal sexual function include aging, socioeconomics, and other medical comorbidities. FSD is common in women throughout their lives and refers to various sexual dysfunctions including diminished arousal, problems achieving orgasm, dyspareunia, and low desire. Its prevalence is reported as high as 20% to 43%.\(^3,4\)

The World Health Organization and the US Surgeon General have released statements encouraging health care providers to address sexual health during a patient’s annual visits.\(^5\) Unfortunately, despite this call to action, many patients and providers are initially hesitant to discuss these problems.\(^6\)

*The Diagnostic and Statistical Manual of Mental Disorders, Fifth edition (DSM-5)* provides the definition and diagnostic...
guidelines for the different components of FSD. Its classification of sexual disorders was simplified and published in May 2013.7 There are now only 3 female dysfunctions as opposed to 5 in DSM-IV.

- Female hypoactive desire dysfunction and female arousal dysfunction were merged into a single syndrome labeled female sexual interest/arousal disorder.
- The formerly separate dyspareunia (painful intercourse) and vaginismus are now called genitopelvic pain/penetration disorder.
- Female orgasmic disorder remains as a category and is unchanged.

To qualify as a dysfunction, the problem must be present more than 75% of the time, for more than 6 months, causing significant distress, and must not be explained by a nonsexual mental disorder, relationship distress, substance abuse, or a medical condition.

Substance- or medication-induced sexual dysfunction falls under “Other Dysfunctions” and is defined as a clinically significant disturbance in sexual function that is predominant in the clinical picture. The criteria for substance- and medication-induced sexual dysfunction are unchanged and include neither the 75% nor the 6-month requirement. The diagnosis of sexual dysfunction due to a general medical condition and sexual aversion disorder are absent from the DSM-5.7

A common symptom. Female sexual disorders can be caused by several complex physiologic and psychological factors. A common symptom among many women is dyspareunia. It is seen more often in postmenopausal women, and its prevalence ranges from 8% to 22%.8 Pain on vaginal entry usually indicates vaginal atrophy, vaginal dermatitis, or provoked vestibulodynia. Pain on deep penetration could be caused by endometriosis, interstitial cystitis, or uterine leiomyomas.9

The physical examination will reproduce the pain when the vulva or vagina is touched with a cotton swab or when you insert a finger into the vagina. The differential diagnosis is listed in the TABLE.8-11

Evaluating the patient
Initially, many patients and providers may hesitate to discuss sexual dysfunction, but the annual exam is a good opportunity to broach the topic of sexual health.

Screening and history
Clinicians can screen all patients, regardless of age, with the help of a validated sex questionnaire or during a routine review of systems. There are many validated screening tools available. A simple, integrated screening tool to use is the Brief Sexual Symptom Checklist for Women (BSSC-W), created by the International Consultation in Sexual Medicine.12 Although recommended by the American Congress of Obstetricians and Gynecologists,9 the BSSC-W is not validated. The questionnaire includes 4 questions that ascertain personal information regarding an individual’s overall sexual function satisfaction, the problem causing dysfunction, how bothersome the symptoms are, and if the patient is interested in discussing it with her provider.12

It’s important to obtain a detailed obstetric and gynecologic history that includes any sexually transmitted diseases, sexual abuse, urinary and bowel complaints, or surgeries. In addition, you’ll want to differentiate between various types of dysfunctions. A thorough physical examination, including an external and internal pelvic exam, can help to rule out other causes of sexual dysfunction.

General examination:
What to look for
The external pelvic examination begins with visual inspection of the vulva, labia majora, and labia minora. Often, this is best accomplished gently with a gloved hand and a cotton swab. This inspection may reveal changes in pubic hair distribution, vulvar skin disorders, lesions, masses, cracks, or fissures. Inspection may also reveal redness and pain typical of vestibulitis, a flattening and pallor of the labia that suggests estrogen deficiency, or pelvic organ prolapse.

The internal pelvic examination begins with a manual evaluation of the muscles of the pelvic floor, uterus, bladder, urethra, anus, and adnexa. Make careful note
of any unusual tenderness or pelvic masses. Pelvic floor muscles (PFMs) should voluntarily contract and relax and are not normally tender to palpation. Pelvic organ prolapse and/or hypermobility of the bladder may indicate a weakening of the endopelvic fascia and may cause sexual pain. The size and flexion of the uterus, tenderness in the vaginal fornix possibly indicating endometriosis, and adnexal fullness and/or masses should be identified and evaluated.

**Neurologic exam of the pelvis** will involve evaluation of sensory and motor function of both lower extremities and include a screening lumbosacral neurologic examination. Lumbosacral examination includes assessment of PFM strength, anal sphincter resting tone, voluntary anal contraction, and perineal sensation. If abnormalities are noted in the screening assessment, a complete comprehensive neurologic examination should be performed.

**It’s important to assess pelvic floor muscle strength**

Sexual function is associated with normal PFM function. The PFMs, particularly the pubococcygeus and iliococcygeus, are responsible for involuntary contractions during orgasm. Orgasm has been considered a reflex, which is preceded by increased blood flow to the genital organs, tumescence of the vulva and vagina, increased secretions during sexual arousal, and increased tension and contractions of the PFMs. Lowenstein et al found that women with strong or moderate PFM contractions scored significantly higher on both orgasm and arousal domains of the female sexual function index (FSFI) compared with women with weak PFM contractions. Orgasm and arousal functions may be associated with PFM strength, with a positive association between pelvic floor strength and sexual activity and function.

The function and dysfunction of the PFMs have been characterized as normal, overactive (high tone), underactive (low tone), and non-functioning.

- **Normal PFMs** are those that can voluntarily and involuntarily contract and relax.
- **Overactive (high-tone)** muscles are those that do not relax and possibly contract during times of relaxation for micturition or defecation. This type of dysfunction can lead to voiding dysfunction, defecatory dysfunction, and dyspareunia.
- **Underactive, or low-tone, PFMs** cannot contract voluntarily. This can be associated with urinary and anal incontinence and pelvic organ prolapse.
- **Nonfunctioning muscles** are completely inactive.

How to assess. There are several ways to assess PFM tone and strength.20 The first is intravaginal or intrarectal digital palpation, which can be performed when the patient is in a supine or standing position. This examination evaluates PFM tone, squeeze pressure during contraction, symmetry, and relaxation. However, there is no validated scale to quantify PFM strength. Contractions can be further divided into voluntary and involuntary.19

During the examination, the physician should ask the patient to contract as much as she can to evaluate the maximum strength and sustained contraction for endurance. This measurement can be done with digital palpation or with pressure manometry or dynamometry.

Examination can be focused on the levator ani, piriformis, and internal obturator muscles bilaterally and rated by the patient’s reactions. Pelvic muscle tenderness, which can be highly prevalent in women with chronic pelvic pain, is associated with higher degrees of dyspareunia.21 Digital evaluation of the pelvic floor musculature varies in scale, number of fingers used, and parameters evaluated. Lukban et al has described a zero to 4 numbered scale that evaluates tenderness in the pelvic floor.22 The scale denotes “1” as comfortable pressure associated with the exam, “2” as uncomfortable pressure associated with the exam, “3” as moderate pain associated with the exam and that intensifies with contraction, and “4” indicating severe pain with the exam and inability to perform the contraction maneuver due to pain.

Effective treatment includes multiple options

Lifestyle modifications can help
Lifestyle changes may help improve sexual function. These modifications include physical activity, healthy diet, nutrition counseling, and adequate sleep.23,24

Identifying medical conditions such as depression and anxiety will help delineate differential diagnoses of sexual dysfunction. Cardiovascular diseases may contribute to arousal disorder as a result of atherosclerosis of the vessels supplying the vagina and clitoris. Neurologic diseases such as multiple sclerosis and diabetes can affect sexual dysfunction by impairing arousal and orgasm. Identification of concurrent comorbidities and implementation of lifestyle changes will help improve overall health and may improve sexual function.25

In addition, Herati et al26 found food sensitivities to grapefruit juice, spicy foods, alcohol, and caffeine were more prevalent in patients with interstitial cystitis and chronic pelvic pain. Avoiding irritants such as soap and other detergents in the perineal region may help decrease dysfunction.27 Finally, foods high in oxalate and other acidic items may cause bladder pain and worsening symptoms of vulvodynia.28

Topical therapies worth considering
Lubricants and moisturizers may help women with dyspareunia or symptoms of vaginal atrophy.

Zestra, for instance, which is applied to the vulva prior to sexual activity, has been proven more effective than placebo for improving desire and arousal.29

Neogyn is a non-hormonal cream containing cutaneous lysate and has been shown to improve vulvar pain in women with vulvodynia. A double-blind placebo-controlled randomized crossover trial followed 30 patients over 3 months and found a significant reduction in pain during sexual activity and a significant reduction in erythema.30

Alprostadil is a prostaglandin E1 analogue that increases genital vasodilation when applied topically and is currently undergoing investigational trials.31,32 Patients can also choose from many over-the-counter lubricants that contain water-based, oil-based, or silicone-based ingredients.

Don’t overlook physical therapy
Manual therapies, including the transvaginal technique, may relieve female sexual dysfunction that results from a variety of causes.
and high-tone pelvic floor dysfunction found it decreased hypertonicity of the pelvic floor and generated statistically significant improvement in the Symptom and Problem Indexes of the O’Leary-Sant Questionnaire, Likert Visual Analogue Scales for urgency and pain, and the Physical and Mental Component Summary from the SF-12 Quality-of-Life Scale. Transvaginal physical therapy is also an effective treatment for myofascial pelvic pain.

Biofeedback, which can be used in combination with pelvic floor physical therapy, teaches the patient to control the PFMs by visualizing the activity to achieve conscious control over contraction of the pelvic floor and ceasing the cycle of spasm. Ger et al investigated patients with levator spasm and found biofeedback decreased pain; relief was rated as good or excellent at 15-month follow-up in 6 out of 14 patients (43%).

Home devices such as Eros Therapy, an FDA-approved, nonpharmacologic battery-operated device, provide vacuum suction to the clitoris with vibratory sensation. Eros Therapy has been shown to increase blood flow to the clitoris, vagina, and pelvic floor and increase sensation, orgasm, lubrication, and satisfaction.

Vaginal dilators allow increasing lengths and girths designed to treat vaginal and pelvic floor pain. In our practice, we encourage pelvic muscle strengthening tools in the form of kegal trainers and other insertion devices that may improve PFM coordination and strength.

Pharmacotherapy has its place

The treatment of FSD may require a multimodal systematic approach targeting genitopelvic pain. But before the best options can be found, it is important to first establish the cause of the pain. Several drug formulations have been effectively used including hormonal and non-hormonal options.

Conjugated estrogens are FDA approved for the treatment of dyspareunia, which can contribute to decreased desire. Systemic estrogen in oral form, transdermal preparations, and topical formulations may increase sexual desire and arousal and decrease dyspareunia. Even synthetic steroid compounds such as tibolone may improve sexual function, although it is not FDA approved for that purpose.

Ospemifene (Osphena) is a selective estrogen receptor modulator that acts as an estrogen agonist in select tissues, including vaginal epithelium. It is FDA approved for dyspareunia in postmenopausal women. A daily dose of 60 mg is effective and safe with minimal adverse effects. Studies suggest that testosterone, although not FDA approved in the United States for this purpose, improves sexual desire, pleasure, orgasm, and arousal satisfaction. The hormone has not gained FDA approval because of concerns about long-term safety and efficacy.

Non-hormonal drugs including flibanserin (Addyi), a well-tolerated serotonin receptor 1A agonist, 2A antagonist shown to improve sexual desire, increase the number of satisfying sexual events, and reduce distress associated with low sexual desire when compared with placebo. The FDA has approved flibanserin as the first treatment targeted for women with hypoactive sexual desire disorder (HSD). It can, however, cause severe hypotension and syncope, is not well tolerated with alcohol, and is contraindicated in patients who take strong CYP3A4 inhibitors, such as fluconazole, verapamil, and erythromycin, or who have liver impairment.

Buproprion, a mild dopamine and noradrenaline reuptake inhibitor and acetylcholine receptor antagonist, has been shown to improve desire in women with and without depression. Although it is FDA approved for major depressive disorder, it is not approved for female sexual dysfunction and is still under investigation.

Tricyclic antidepressants such as nortriptyline and amitriptyline may be effective in treating neuropathic pain. Starting doses of both amitriptyline and nortriptyline are 10 mg/d and can be increased to a maximum of 100 mg/d. Tricyclic antidepressants are still under investigation for the treatment of FSD.

Muscle relaxants in oral and topical compounded form are used to treat increased pelvic floor tension and spasticity. Cyclobenzaprine and tizanidine are FDA-
approved muscle relaxants indicated for muscle spasticity.

- **Cyclobenzaprine**, at a starting dose of 10 mg, can be taken up to 3 times a day for pelvic floor tension. Tizanidine is a centrally active alpha 2 agonist that is superior to placebo in treating high-tone pelvic floor dysfunction.44

- **Other medications include** benzodiazepines such as oral clonazepam and intravaginal diazepam, although they are not FDA approved for high-tone pelvic floor dysfunction. Rogalski et al reviewed 26 patients who received vaginal diazepam for bladder pain, sexual pain, and levator hypertonus.45 They found subjective and sexual pain improvement assessed on FSFI and the visual analog pain scale. PFM tone significantly improved during resting, squeezing, and relaxation phases. Multimodal therapy can be used for muscle spasticity and high-tone pelvic floor dysfunction.

### Trigger point and Botox injections

Although drug therapy has its place in the management of sexual dysfunction, other modalities that involve trigger point injections or botulinum toxin injections to the PFM may prove helpful for patients with high-tone pelvic floor dysfunction.

A prospective study investigated the role of trigger point injections in 18 women with levator ani muscle spasm with a mixture of 0.25% bupivacaine in 10 mL, 2% lidocaine in 10 mL, and 40 mg of triamcinolone in 1 mL combined and used for injection of 5 mL per trigger point.46 Three months after injections, 13 of the 18 women improved, resulting in a success rate of 72%. Trigger point injections can be applied externally or transvaginally.

- **OnabotulinumtoxinA** (Botox) has also been tested for relief of levator ani muscle spasm. Botox is FDA approved for upper and lower limb spasticity but is not approved for pelvic floor spasticity or tension. It may reduce pressure in the PFM and may be useful in women with high-tone pelvic floor dysfunction.47

In a prospective 6-month pilot study, 28 patients with pelvic pain who failed conservative treatment received up to 300 U Botox into the pelvic floor.47 The study, which used needle electromyography guidance and a transperineal approach, found that the dyspareunia visual analog scale improved significantly at Weeks 12 and 24. Keep in mind, however, that onabotulinumtoxinA should be reserved for patients who fail conventional treatments.47,48

### Addressing psychological issues

Sex therapy is a traditional approach that aims to improve individual or couples’ sexual experiences and help reduce anxiety related to sex.42 Cognitive behavioral sex therapy includes traditional sex therapy components but puts greater emphasis on modifying thought patterns that interfere with intimacy and sex.42

Mindfulness-based cognitive-behavioral treatments have shown promise for sexual desire problems. It is an ancient eastern practice with Buddhist roots. This therapy is a nonjudgmental, present-moment awareness comprised of self-regulation of attention and accepting orientation to the present.49 Although there is little evidence from prospective studies, it may benefit women with sexual dysfunction after intervention with sex therapy and cognitive behavioral therapy.

Female sexual dysfunction is common and affects women of all ages. It can negatively impact a women’s quality of life and overall well-being. The etiology of FSD is complex, and treatments are based on the causes of the dysfunction. Difficult cases warrant referral to a specialist in sexual health and female pelvic medicine. Future prospective trials, randomized controlled trials, the use of validated questionnaires, and meta-analyses will continue to move us forward as we find better ways to understand, identify, and treat female sexual dysfunction.
